# Motivation

---

- Nonequilibrium atmospheric pressure air plasmas are of interest in a variety of applications such as electromagnetic wave shielding and bio-decontamination.
- Large volumes, relatively low temperatures ( $\leq 2000$  K) and high electron number densities ( $n_e \geq 10^{12} \text{ cm}^{-3}$ ) are desired.

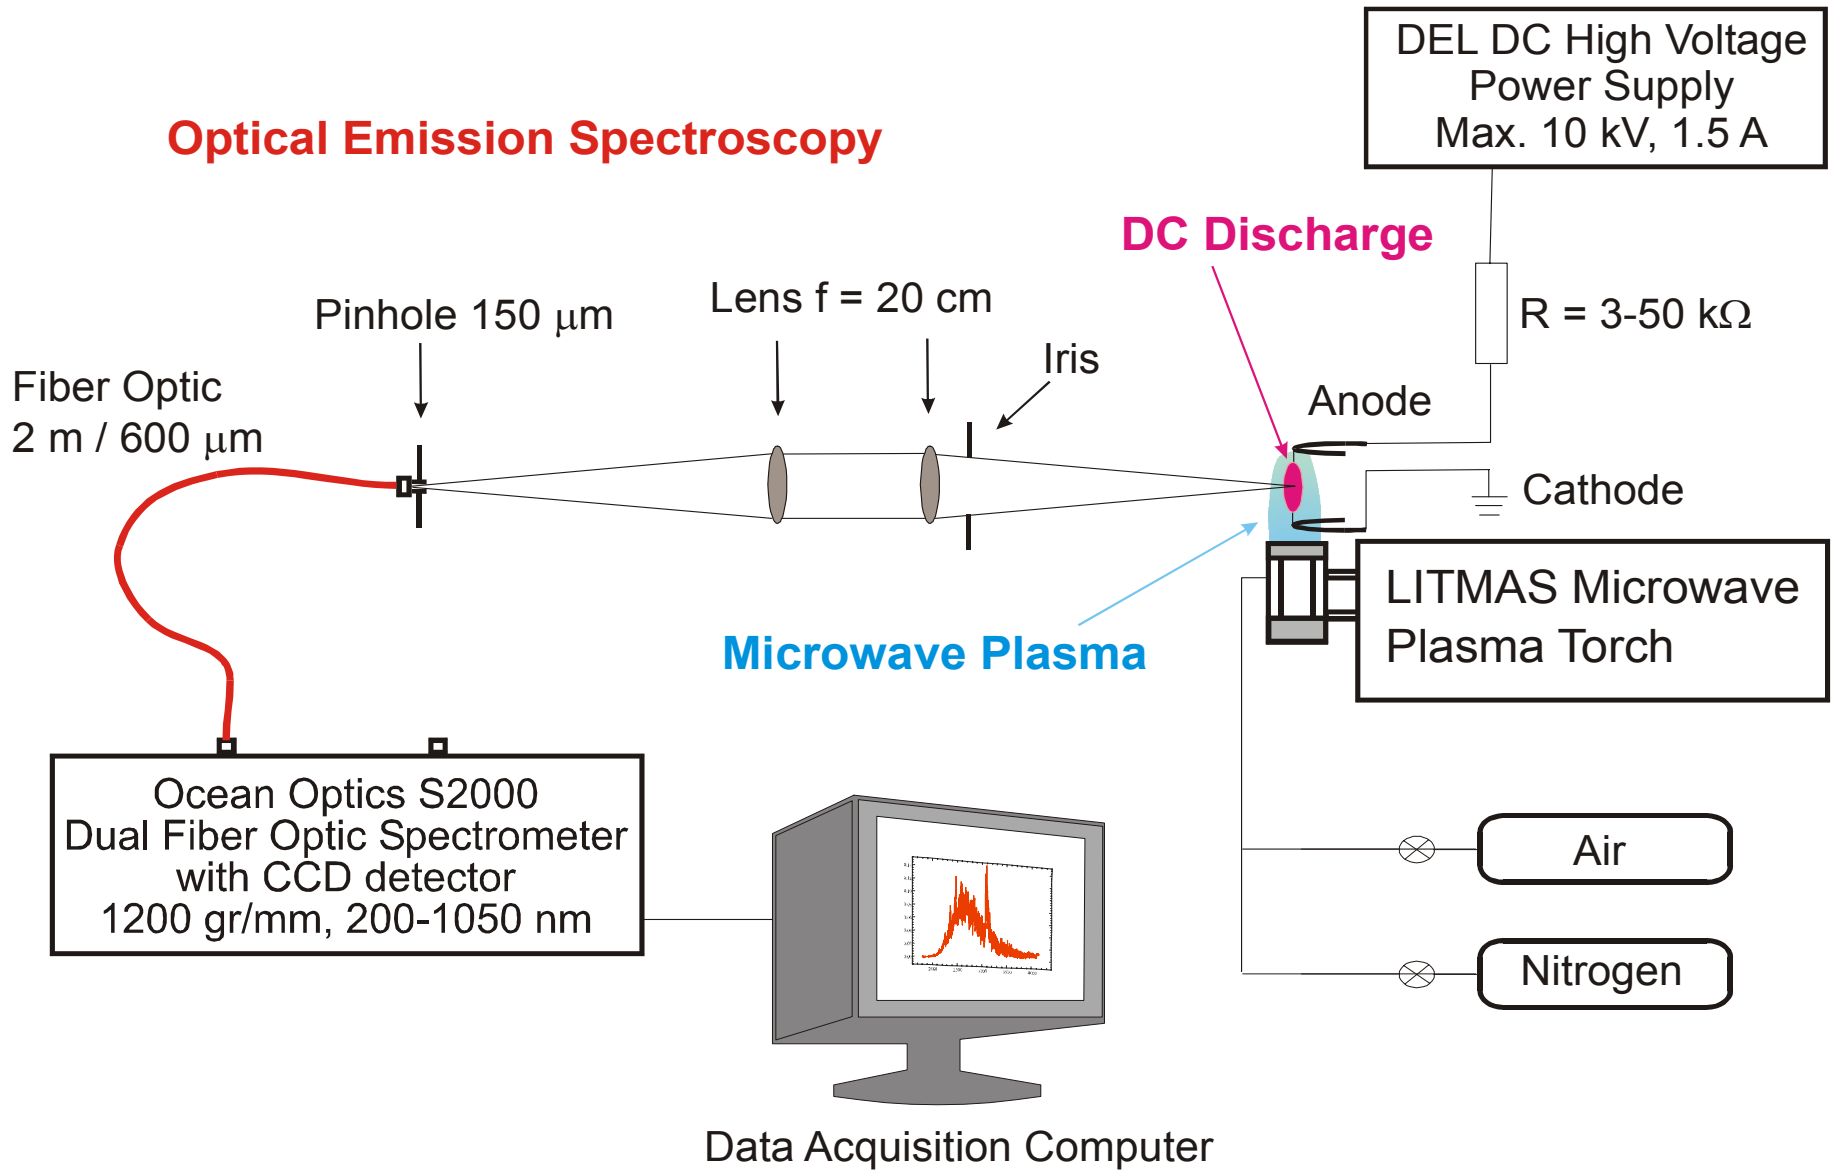

# Approach

---

- Microwave torch air plasmas
  - DC discharge air plasmas
- 
- Study DC discharges in microwave preheated air

# Experimental Setup

## Optical Emission Spectroscopy

# Optical Emission Spectroscopy of Air Plasmas

Emission Spectrum of Equilibrium Air at 1 atm with 1.3% H<sub>2</sub>O, 1 cm slab

- LTE Air: Absolute emission intensity depends on the temperature
- N<sub>2</sub> (C-B) 2<sup>nd</sup> positive, N<sub>2</sub> (B-A) 1<sup>st</sup> positive, N<sub>2</sub><sup>+</sup> (B-X) 1<sup>st</sup> negative systems:
  - T > 6000 K in LTE air
  - Commonly observed in nonequilibrium discharges

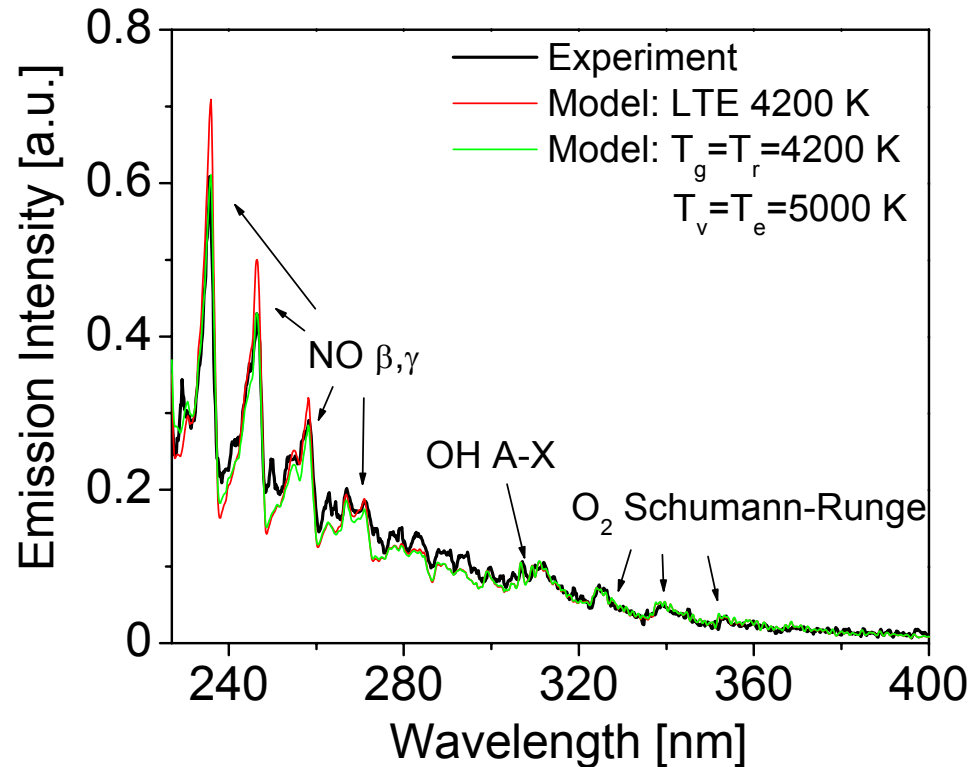

# Microwave Air Plasma

## 1) Low Flow Rate, High Temperature Case

Air Flow Rate: 9 SLPM  
MW Power: 1.5 kW  
Energy Density: 10,000 J/l  
Flow Velocity: ~27 m/s

- Temperature measured from relative intensity spectral fit

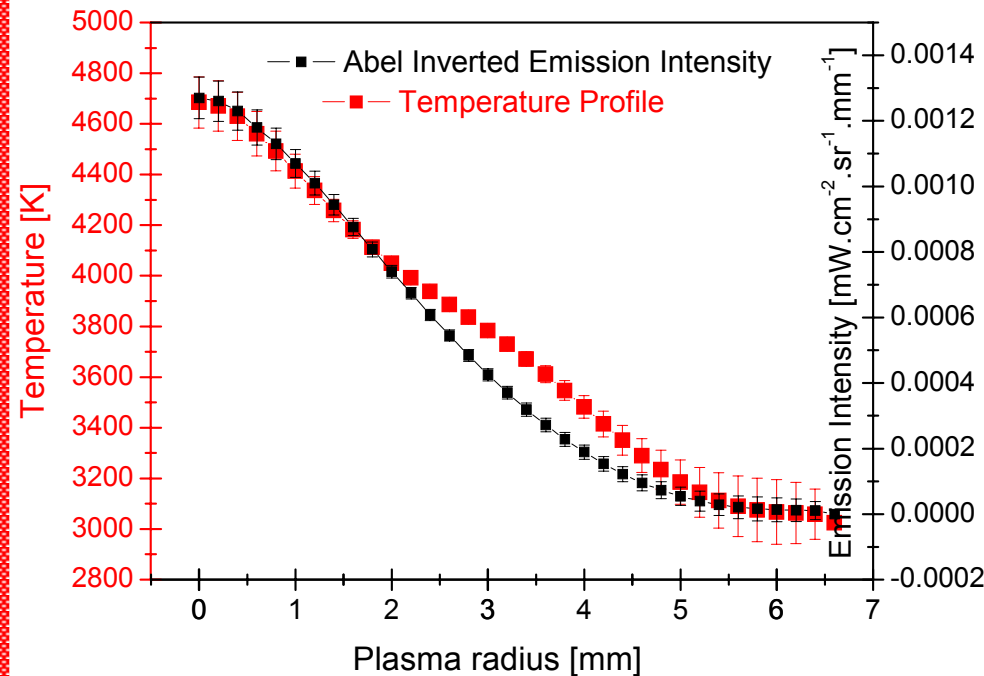

Plasma close to LTE,  $T_{LTE} \sim 4200$  K

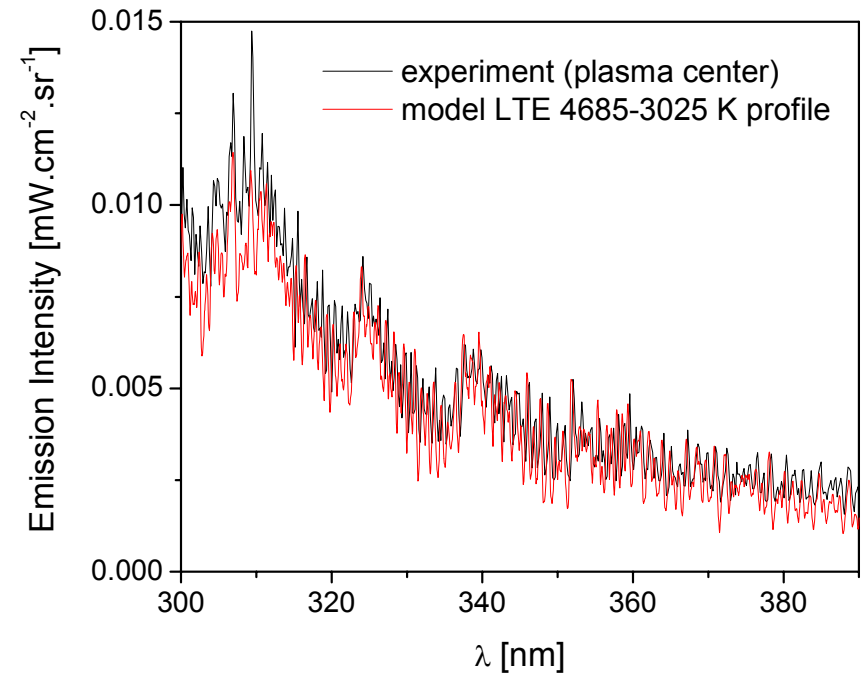

# Microwave Air Plasma - Temperature Profile

## 2) Low Flow Rate, Highest Temperature Case

- Temperature profile measured from absolute intensity  $O_2$  spectra

### $O_2$ Schumann-Runge bands fit:

Air Flow Rate: 8 SLPM  
MW Power: 1.75 kW  
Energy Density: 12,900 J/l  
Flow Velocity: ~17 m/s

Plasma close to LTE,  $T_{LTE} \sim 4700$  K

# Microwave Air Plasma

## 3) High Flow Rate, Low Temperature Case

Air Flow Rate: 110 SLPM  
Injected MW Power: 2.1 kW  
Energy Density: 1100 J/l  
Flowing Velocity: ~120 m/s

# Microwave Air Plasma - Temperature

## 4) High Flow Rate, Lowest Temperature Case

Low Temperature → Low Emission Intensity → No detectable spectrum

Solution: apply Corona Discharge to enhance emission locally

### Corona Discharge:

➤ does not heat gas

$$(T_{\text{gas}} \approx T_{\text{ambient}}, T_e \gg T_{\text{gas}})$$

➤ produces weak but detectable

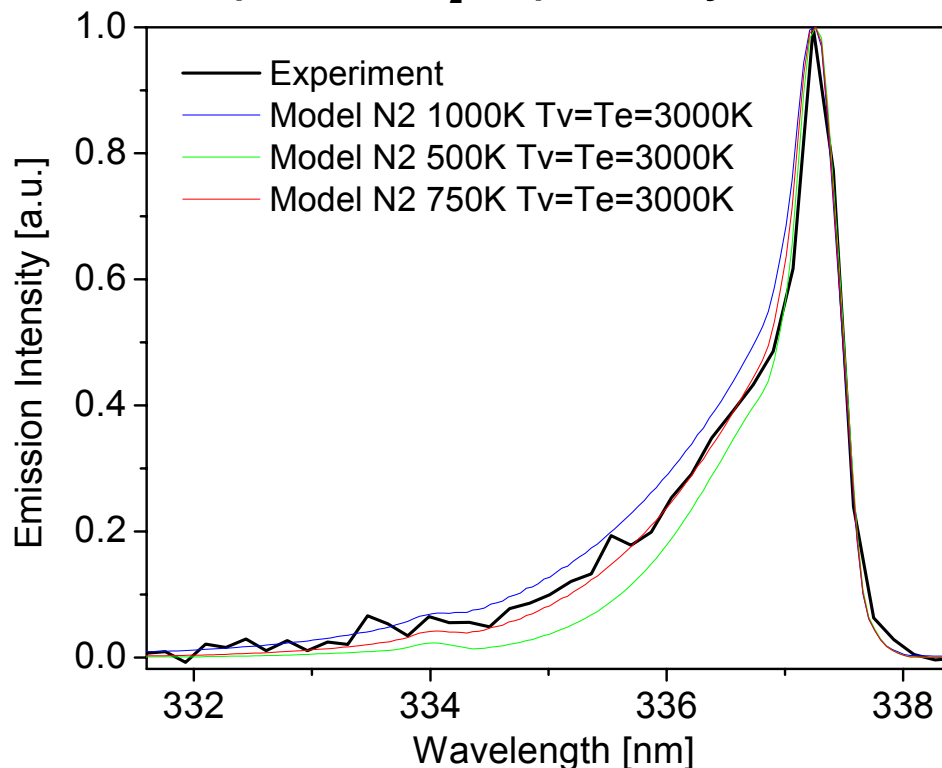

$\text{N}_2$  spectrum (2<sup>nd</sup> positive system)

➤ Temperature measured from relative intensity  $\text{N}_2$  C-B spectra

Air Flow Rate: 110 SLPM  
Injected MW Power: 1.5 kW  
Energy Density: 800 J/l  
Flowing Velocity: ~60 m/s

Corona spectrum –  $\text{N}_2$  2<sup>nd</sup> positive system, 0-0 band

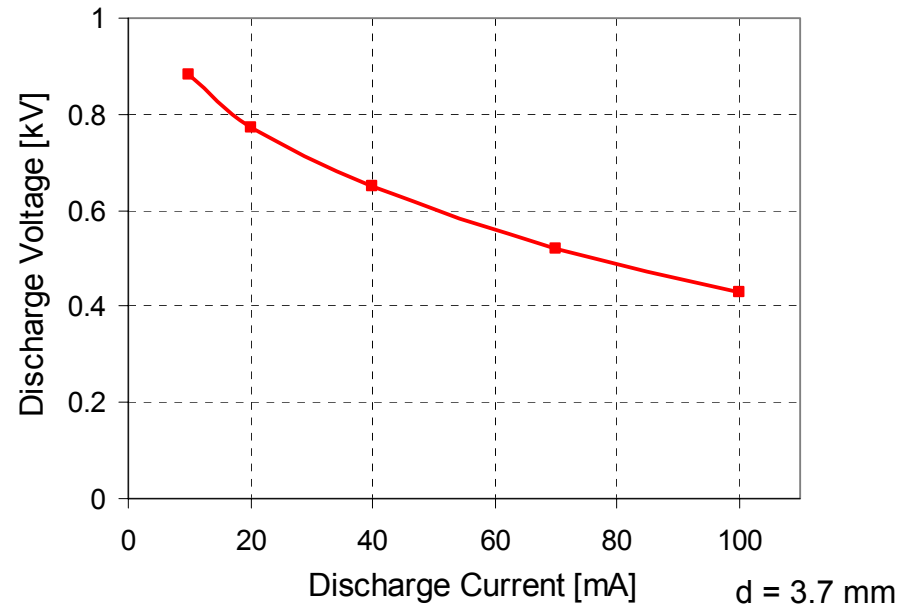

Nonequilibrium plasma minimum  $T_{\text{rot}} \sim 750 \text{ K}$

# DC Discharge in Ambient Air

Low gas flow rate  
Flow velocity:  $\sim 1-10$  m/s  
Current: 5-100 mA  
Interelectrode distance: 0.1-10 cm

- Current-Voltage Characteristic has a negative slope
- Temperature measured from relative intensity  $N_2$  C-B spectra

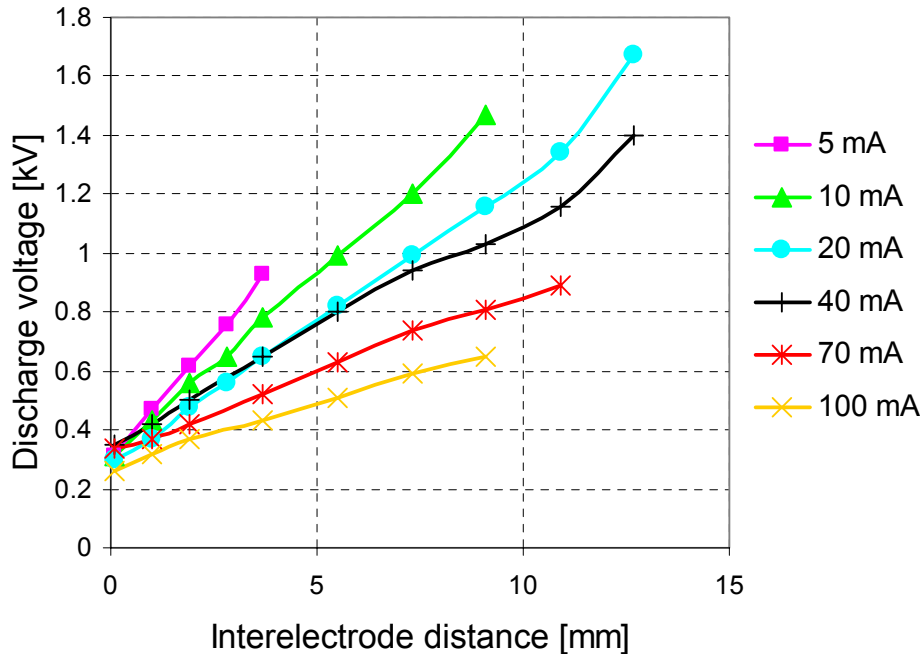

Nonequilibrium plasma

$T_{rot} \sim 1500-3000$  K

$T_{vib} \sim 4000$  K

# DC Discharge in Ambient Air

## Electric field and Electron density

- Electric field in the DC discharge column decreases with increasing current
- Higher  $I \rightarrow$  higher  $T_{\text{gas}}$ , closer to  $T_e \rightarrow$  lower gas density  $\rightarrow$  lower  $E$

$T_e$  and  $n_e$  can be related to  $E$  and  $j$  by Ohm's law and the electron energy equation

$$I = 10 \text{ mA}$$

$$j \approx 1.3 \text{ A cm}^{-2}$$

$$T_{\text{gas}} \approx 2000 \text{ K}$$

$$n_e \approx 8 \times 10^{11} \text{ cm}^{-3}$$

# DC Discharge in Microwave Plasma

- Microwave plasma enables study of DC discharges in preheated air
- **Reduced electron attachment** in DC discharge for  $T_{\text{gas}} > 1500 \text{ K}$
- Temperature measured from relative intensity  $\text{N}_2$  C-B spectra

Wide range of gas flow rate  
Flow velocity:  $\sim 10\text{-}160 \text{ m/s}$   
Current:  $5\text{-}150 \text{ mA}$   
Interelectrode distance:  $0.1\text{-}10 \text{ cm}$

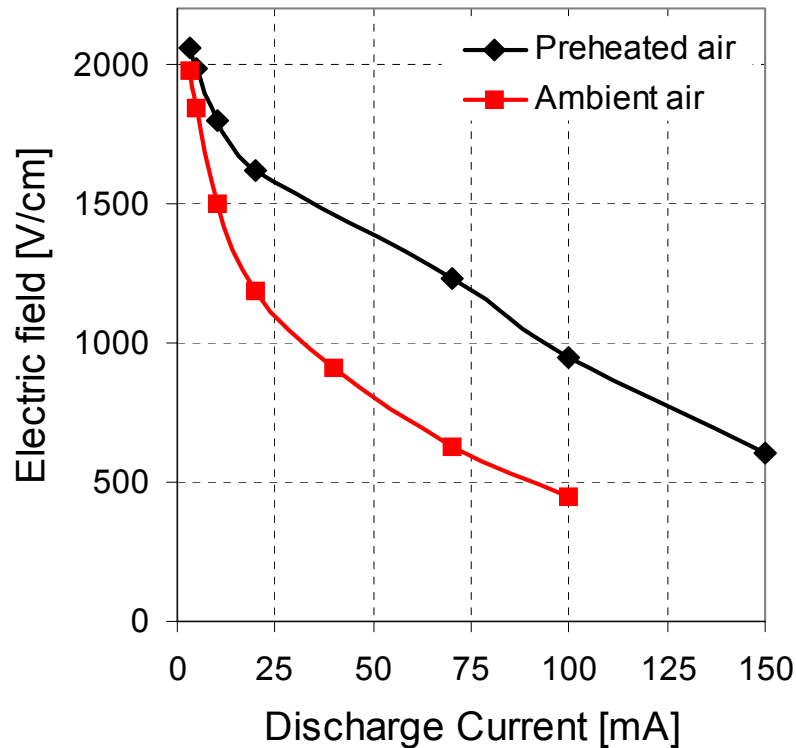

**Nonequilibrium plasma**

$T_{\text{rot}} \sim 1500\text{-}3000 \text{ K}$

$T_{\text{vib}} \sim 4000 \text{ K}$

# DC Discharge in Microwave Plasma

## Electric field and Electron density

- Electric field in the DC discharge column decreases with increasing current

Higher  $I$

↓  
higher  $T_{\text{gas}}$ , closer to  $T_e$

↓  
lower gas density

↓  
lower  $E$

- Strong flow of preheated air prevents the discharge to heat up

- Lower  $T$  and higher  $E$  than in ambient air discharge for a given current

$$I = 40 \text{ mA}$$

$$j \approx 3 \text{ A cm}^{-2}$$

$$T_{\text{gas}} \approx 2000 \text{ K}$$

$$n_e \approx 2 \times 10^{12} \text{ cm}^{-3}$$

# Conclusions

---

Three approaches to generate air plasmas:

➤ **Microwave Torch**

- Nonequilibrium plasmas
- Near-LTE Plasmas
- $T \sim 750-4700$  K
- Flow velocities 10-100 m/s

➤ **DC Discharge**

- Nonequilibrium plasmas
- $T \sim 1500-3000$  K
- Flow velocities 1-10 m/s
- $T_{\text{gas}}$  depends strongly on  $I$

➤ **Coupled Microwave and DC Discharge**

- Nonequilibrium plasmas
- $T \sim 1000-5000$  K, optimum 2000 K
- Flow velocities 10-160 m/s
- Enables to decouple  $T_{\text{gas}}$  from  $I$
